Recruitment of Human Microvascular Endothelial Cells from Human Bone Marrow to Mouse Venules in an Experimental Model of Severe Sepsis. Severe sepsis is a life-threatening condition that causes organ dysfunction and death. There are no therapies proven to improve survival in patients with sepsis. The purpose of this study was to determine whether endothelial progenitor cells (EPCs) were mobilized to the circulation and whether their recruitment to the site of sepsis could be enhanced. The experimental model of sepsis was induced in mice by intraperitoneal injection of live Escherichia coli. At the time of death, mice were treated with EPCs (EPC-treated mice) or vehicle (control mice). At 24 hours after sepsis, human microvascular endothelial cells (HBMECs) were injected into the mouse jugular vein and their presence in venules was examined. Another group of mice was treated with an antibody that targets stem cell factor (SCF) and assessed in the same manner. The presence of HBMECs in the jugular vein was assessed by immunohistochemical staining. The number of HBMECs was significantly higher in EPC-treated mice (6.15 ± 2.16) than control mice (2.06 ± 0.72) (P < 0.05).
